

Muon magnetic anomaly measurement to 0.46 ppm at FNAL

Alberto Lusiani, for the FNAL Muon $g-2$ collaboration
Scuola Normale Superiore and INFN, sezione di Pisa

Research Progress Meeting seminar at LBNL
April 20, 2021

BERKELEY LAB

Introduction

for a particle p such as a muon, electron, proton, neutron

- magnetic moment $\vec{\mu}_p = g_p \frac{e}{2m_p} \vec{S}_p$, $e = \text{absolute value of electron charge}$
 $\vec{S}_p = \text{spin or particle intrinsic angular momentum}$
 $g_p = \text{gyromagnetic ratio}$ (defined also for neutral particles)
- $g_e, g_\mu \simeq -2$, $g_p \simeq 5.6$, $g_n \simeq -3.8$
- in the following, absolute values are used for simplicity

muon (or electron, tau)

- $g_\mu = 2$ Dirac equation, or leading order relativistic quantum mechanics
- $g_\mu > 2$ when adding higher order contributions
- $a_\mu = \frac{g_\mu - 2}{2}$ muon anomalous gyromagnetic ratio or magnetic anomaly

a_μ measured a_μ prediction is a powerful test of the Standard Model

- sub-ppm Standard Model prediction
- sub-ppm experimental measurement
- sensitive to all particles and forces via quantum loops

First g_μ measurement (1957)

motivation: confirm Lee & Yang predictions about parity violation in pion and muon decay

Observations of the Failure of Conservation of Parity and Charge Conjugation in Meson Decays: the Magnetic Moment of the Free Muon*

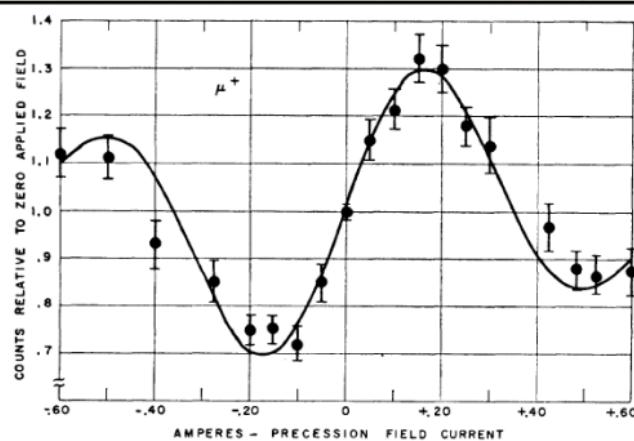

RICHARD L. GARWIN,[†] LEON M. LEDERMAN,
AND MARCEL WEINRICH

*Physics Department, Nevis Cyclotron Laboratories,
Columbia University, Irvington-on-Hudson,
New York, New York
(Received January 15, 1957)*

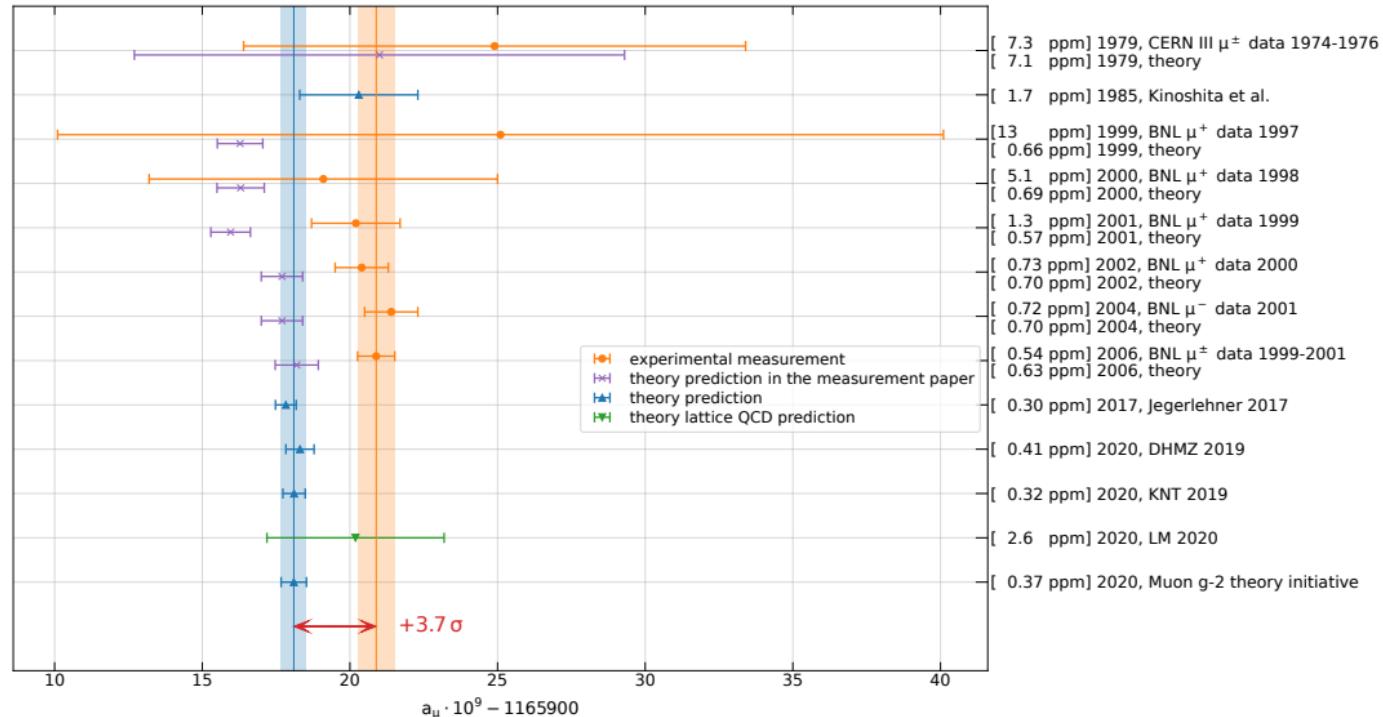

LEE and Yang¹⁻³ have proposed that the long held space-time principles of invariance under charge conjugation, time reversal, and space reflection (parity) are violated by the "weak" interactions responsible for decay of nuclei, mesons, and strange particles. Their hypothesis, born out of the $\tau-\theta$ puzzle,⁴ was accompanied by the suggestion that confirmation should be sought (among other places) in the study of the successive reactions

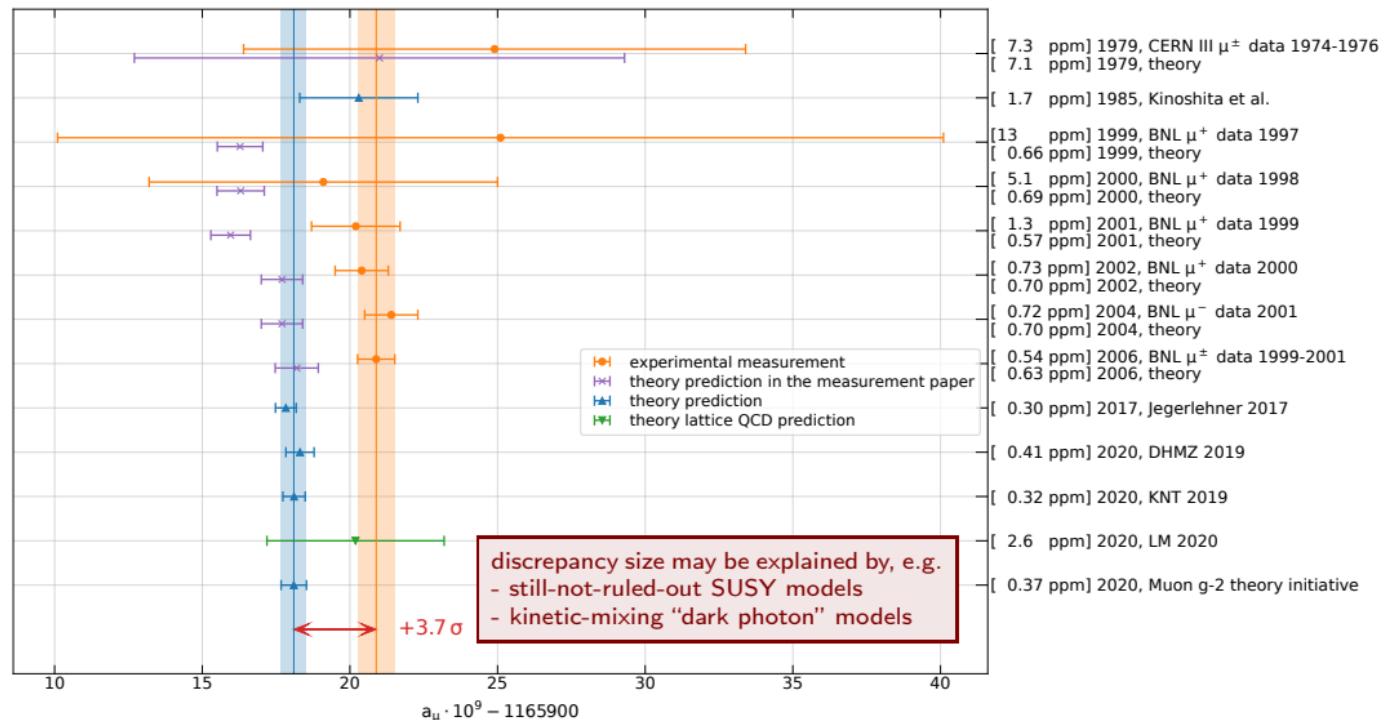

$$\pi^+ \rightarrow \mu^+ + \nu, \quad (1)$$

$$\mu^+ \rightarrow e^+ + 2\nu. \quad (2)$$

- ▶ forward pion-decay muons are highly polarized
- ▶ μ -decay electrons angular asymmetry vs. μ spin
- ▶ electron rate vs. B field applied to muons
- ▶ $g_\mu = 2.01 \pm 0.01$

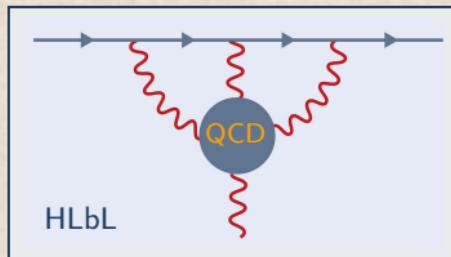

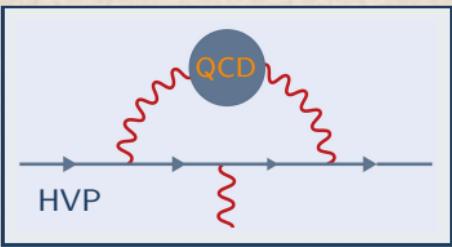

a_μ measurements and predictions 1979 – March 2021 (incomplete collection)

a_μ measurements and predictions 1979 – March 2021 (incomplete collection)

a_μ theory prediction status: 0.37 ppm precision

- ▶ Muon $g-2$ theory initiative White Paper, [Phys. Rept. 887 \(2020\) 1-166](#)
- ▶ consensus of large community of physicists after several years of collaboration
- ▶ significant recent progress on dispersive exp-data-driven calculation of HLbL contribution

contributions		uncertainty [ppb]
QED	complete calculation to 5th order	1
EW	calculation to NLO	10
QCD	primarily non-perturbative	
- HVP	primarily dispersive to NNLO	340
- HLbL	dispersive to NNLO + lattice	150
total		370

a_μ Standard Model test more powerful than a_e for QCD and New Physics

a_μ test $\sim 2000 \times$ less precise than a_e
for experimental and theory uncertainties

$$\frac{\delta_{[\text{Exp} + \text{Th}]} a_\mu}{\delta_{[\text{Exp} + \text{Th}]} a_e} \sim 2000$$

but

a_μ test $\sim 43000 \times$ more sensitive than a_e
for "typical" New Physics models and QCD

$$\frac{\delta_{[\text{New Physics}]} a_\mu}{\delta_{[\text{New Physics}]} a_e} \sim \frac{m_\mu^2}{m_e^2} \simeq 43000$$

experiment and theory uncertainties contributions to a_μ test as of March 2021

	δa_μ [ppm]	δa_e [ppb]
experiment	0.54	0.24
theory	0.37	0.20
- α_{QED}	0.00	0.20
- QED	0.00	0.01
- EW	0.01	0.00
- QCD	0.37	0.01
- HVP	0.34	
- HLbL	0.15	

- ▶ note: using less precise α_{QED} (Cs 2018) because of inconsistency with α_{QED} (Rb 2020)

a_μ measurement method

muon spin precession relative to momentum

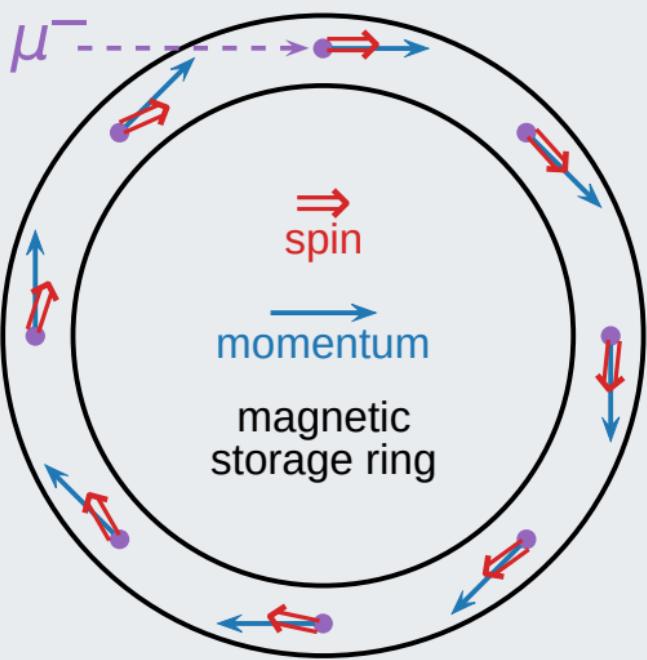

$$\omega_s - \omega_c = \omega_a$$

$$-g_\mu \frac{eB}{2m_\mu} - (1-\gamma) \frac{eB}{m_\mu \gamma} - \frac{eB}{m_\mu \gamma} = -a_\mu \frac{eB}{m_\mu}$$

Larmor + Thomas precessions cyclotron frequency no $\gamma!$

- ▶ frequency measurements best for precision
- ▶ magnetic field NMR measurement also frequency

polarized muons in magnetic storage ring

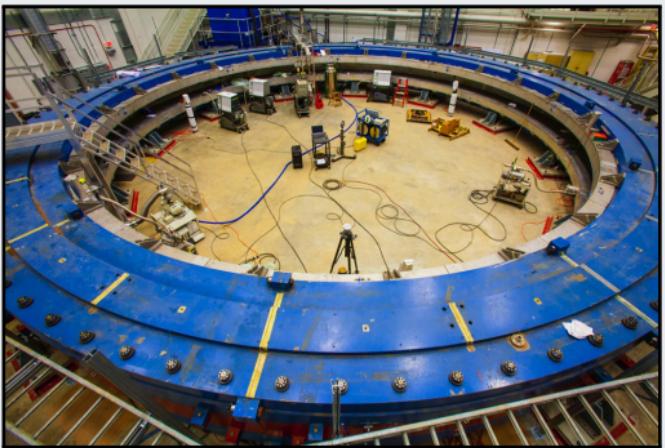

Focusing electric field and magic energy

in presence of (focusing) electric field and motion not perfectly transverse to magnetic field

$$\vec{\omega}_a = -\frac{e}{m_\mu} \left[a_\mu \vec{B} - \left(a_\mu - \frac{1}{\gamma^2 - 1} \right) (\vec{\beta} \times \vec{E}) - a_\mu \frac{\gamma}{\gamma + 1} (\vec{\beta} \cdot \vec{B}) \vec{\beta} \right]$$

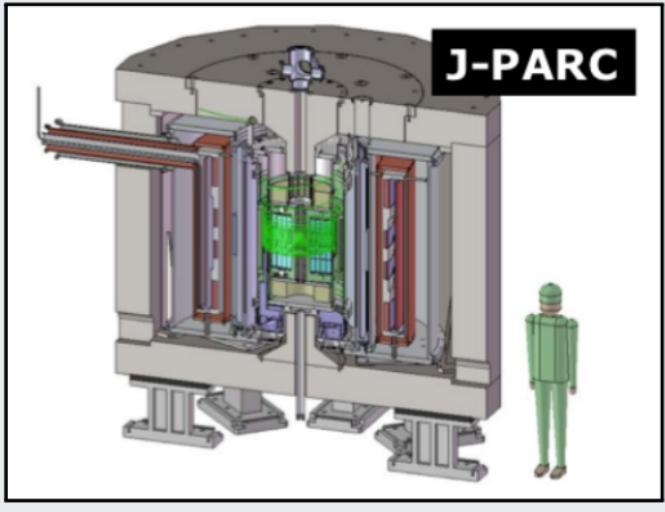

CERN 1975-, BNL, FNAL

$$\begin{aligned} p_\mu^{\text{magic}} &= 3.094 \text{ GeV} \Rightarrow \gamma = 29.3 \\ \Rightarrow \quad &\left(a_\mu - \frac{1}{\gamma^2 - 1} \right) \simeq 0 \end{aligned}$$

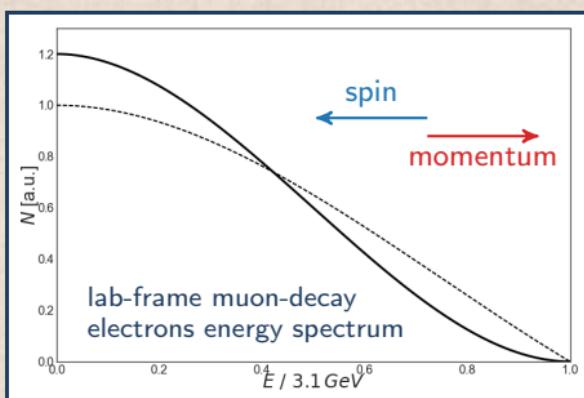

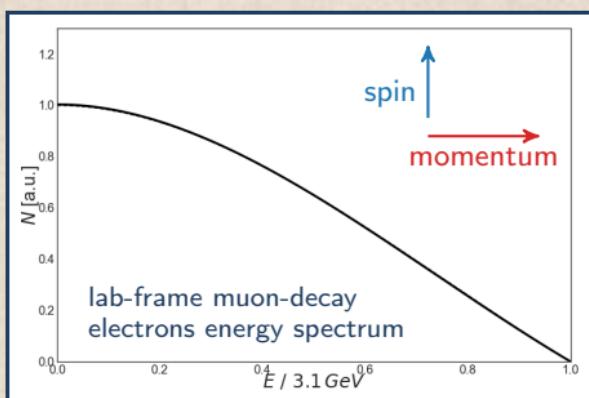

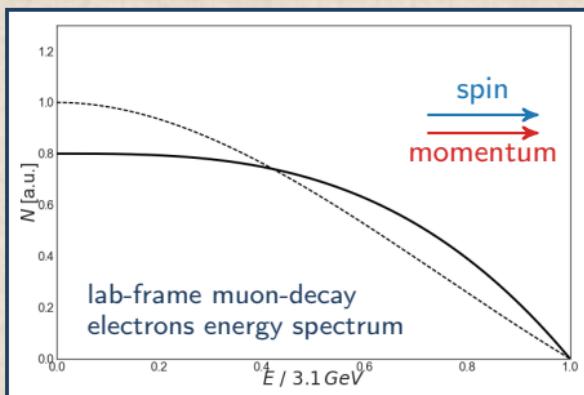

J-PARC E34

ultra-cold muons
 $E = 0 \Rightarrow \vec{\beta} \times \vec{E} = 0$

Rate of high-energy muon-decay electrons modulated with $\cos \omega_a t$

- ▶ because of parity violation in muon decay, decay electrons peak along muon spin
- ▶ electrons decaying along muon momentum have highest energy in lab frame
- ▶ high-energy electrons rate $\propto (1 + A \cos \omega_a t)$

a_μ measurement method**measurement of magnetic field: ω_p**

- ▶ proton spin precession frequency measures magnetic field (NMR): $\hbar\omega_p = 2\mu_p B$

 a_μ measurement

- ▶ using: $\mu_{e,\mu,p} = g_{e,\mu,p} \frac{e}{2m_{e,\mu,p}} S_{e,\mu,p}$, $S_{e,\mu,p} = \hbar/2$

$$a_\mu = \frac{\omega_a}{\omega_p} \cdot \left(\frac{\mu_p}{\mu_e} \frac{m_\mu}{m_e} \frac{g_e}{2} \right)$$

BNL E821 a_μ uncertainties	
ω_a statistical	460 ppb
ω_a systematic	210 ppb
ω_p systematic	170 ppb
$\left(\frac{\mu_p}{\mu_e} \frac{m_\mu}{m_e} \frac{g_e}{2} \right)$	~negligible
a_μ	540 ppb

- ▶ (BNL E821 used a slightly different but equivalent procedure using μ_p/μ_μ instead of μ_p/μ_e)

good approximation, with negligible differences, of ideal metrology procedure

- ▶ actual metrology input in CODATA fit from muon $g-2$ measurements is $R_\mu = \omega_a/\omega_p$
- ▶ to obtain a_μ from R_μ one should do a special CODATA fit using just that R_μ input

FNAL Muon $g-2$ project (a.k.a. FNAL-E989)

	BNL E821	FNAL E989	
ω_a statistical	460 ppb	100 ppb	$\times 21$ detected muon decays ($1.6 \cdot 10^{11}$)
ω_a systematic	210 ppb	70 ppb	faster calorimeter with laser calibration, tracker
ω_p systematic	170 ppb	70 ppb	more uniform B , improve NMR measurement
conversion factor	negligible	negligible	
total	540 ppb	140 ppb

7 countries

BNL storage ring magnet moved to FNAL in 2013 (35 days long trip)

Storage ring magnet adjusted for maximum uniformity

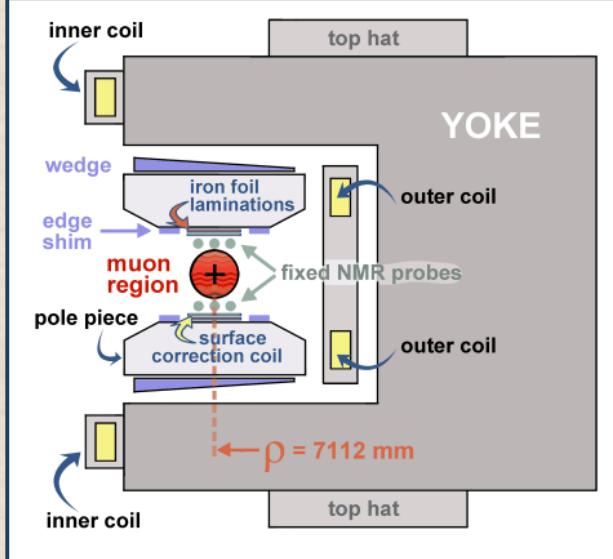

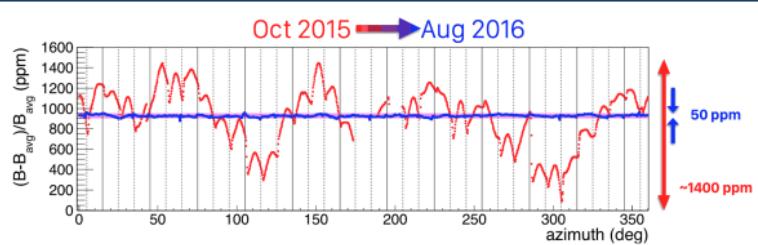

wedging and shimming

- ▶ magnet adjusted to obtain 50 ppm field uniformity
- ▶ 3x better than at BNL

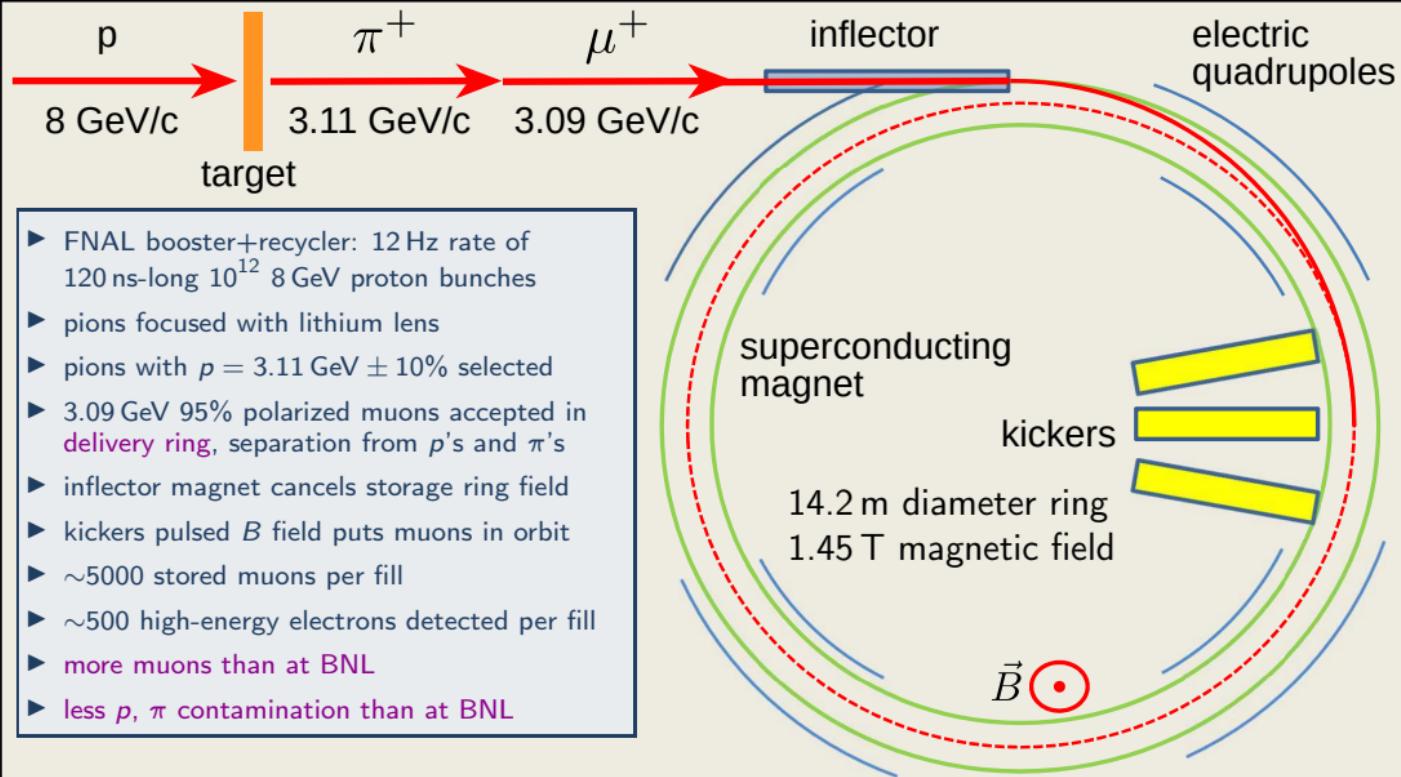

adjustements and insertions

- ▶ 72 poles
- ▶ 864 wedges
- ▶ 24 iron top hats
- ▶ 8000 surface iron foils

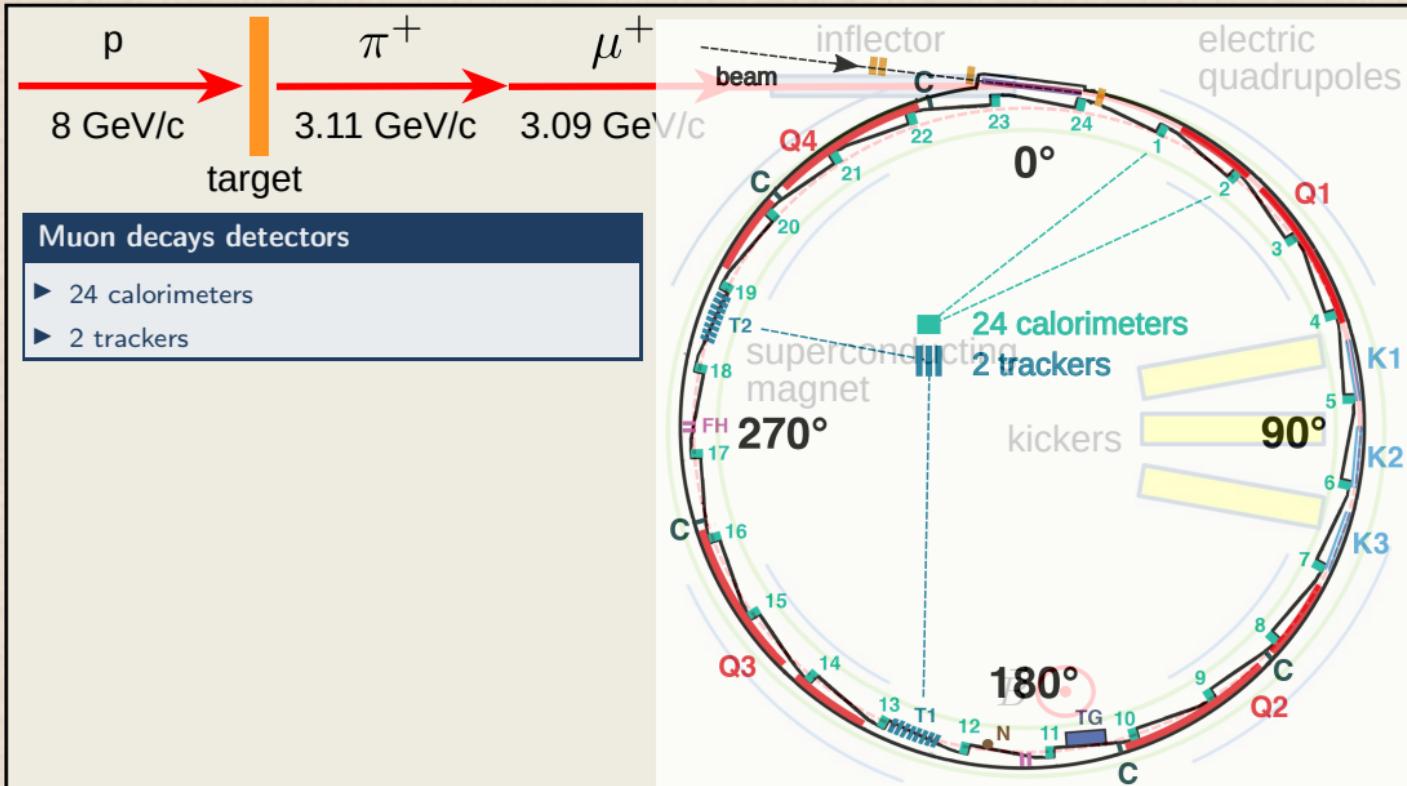

deviation from nominal magnetic field

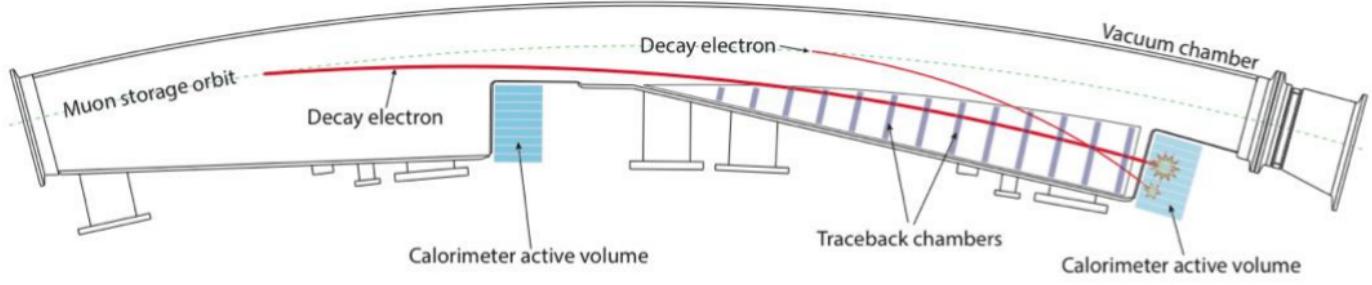

Muon production, storage and decay at FNAL

Muon production, storage, decay and detection at FNAL

Muon decays detectors

- ▶ 24 calorimeter modules of 6×9 PbF_2 crystals with 800 MHz-sampling SiPM readout
 - ▶ measure muon-decay electrons energy detecting Cherenkov light
 - ▶ accurate gain monitoring with **laser calibration system**
- ▶ 2 straw chamber trackers with total of about 1000 channels
 - ▶ reconstruct beam distribution inside storage ring from muon decay electrons

comparison with E821

- ▶ more granular calorimeter, faster data acquisition
- ▶ improved calorimeter gain monitoring
- ▶ improved tracking

Measurement formula in more detail

$$a_\mu = \left[\frac{\omega_a}{\tilde{\omega}'_p(T)} \right] \cdot \left[\frac{\mu'_p(T)}{\mu_e(H)} \right] \left[\frac{\mu_e(H)}{\mu_e} \right] \left[\frac{m_\mu}{m_e} \right] \left[\frac{g_e}{2} \right]$$

measurements by the Muon $g -$ collaboration

- ▶ ω_a precession of muon spin relative to momentum rotation in magnetic field
- ▶ $\tilde{\omega}'_p(T)$ precession frequency of shielded proton spin in spherical water sample at $T = 34.7^\circ\text{C}$ in muon-beam-weighted magnetic field, $\tilde{\omega}'_p(T) = \langle \omega'_p(T)(x, y, \varphi) \times M(x, y, \varphi) \rangle$

notation

- ▶ $\mu'_p(T)$ magnetic momentum of proton in spherical water sample at 34.7°C
- ▶ $\mu_e(H)$ magnetic momentum of electron in hydrogen atom

external measurements

- ▶ $\mu'_p(T)/\mu_e(H)$ 10.5 ppb precision, Metrologia 13, 179 (1977)
- ▶ $\mu_e(H)/\mu_e$ 5 ppq (negligible) theory QED calculation, Rev. Mod. Phys. 88 035009 (2016)
- ▶ m_μ/m_e 22 ppb precision CODATA 2018 fit, primarily driven by LAMPF 1999 measurements of muonium hyperfine splitting, Phys. Rev. Lett. 82, 711 (1999)
- ▶ $g_e/2$ 0.28 ppt (negligible), Phys. Rev. Lett. 100, 120801 (2008)

Conceptual formula for $R'_\mu(T) = \omega_a/\tilde{\omega}'_p(T)$

$$R'_\mu(T) = \frac{\omega_a}{\tilde{\omega}'_p(T)} \underset{\text{conceptually}}{=} \frac{f_{\text{clock}} \omega_a^m (1 + C_e + C_p + C_{\text{ml}} + C_{\text{pa}})}{f_{\text{calib}} \langle \tilde{\omega}'_p(T)(x, y, \varphi) \times M(x, y, \varphi) \rangle (1 + B_k + B_q)}$$

ω_a measurement and corrections

- ▶ f_{clock} correction for blinding clock offset
- ▶ ω_a^m measured precession of muon spin relative to momentum rotation in magnetic field
- ▶ C_e ω_a electric field correction
- ▶ C_p ω_a pitch correction (vertical beam oscillations)
- ▶ C_{ml} ω_a muon loss correction
- ▶ C_{pa} ω_a phase acceptance correction

$\tilde{\omega}'_p(T)$ measurement and corrections

- ▶ f_{calib} magnetic field probes calibration
- ▶ $\tilde{\omega}'_p(x, y, \varphi)$ measured shielded proton spin precession frequency map in storage ring
- ▶ $M(x, y, \varphi)$ muon beam distribution
- ▶ B_k $\tilde{\omega}'_p(T)$ kicker eddy fields correction
- ▶ B_q $\tilde{\omega}'_p(T)$ electric quadrupoles transient field correction

Run 1 data samples

muon decays

Dataset	# Days (Apr-Jun 2018)	Tune (n)	Kicker (kV)	# fills [10 ⁴]	# positrons [10 ⁹]
1a	3	0.108	130	151	0.92
1b	7	0.120	137	196	1.28
1c	9	0.120	132	333	1.98
1d	24	0.107	125	733	4.00

Total of 8.2 billion positrons ($\sim 1.2 \times$ BNL), $\sim 6\%$ of E989 goal of $21 \times$ BNL
4 run periods with different kickers and quadrupoles settings, hence different beam dynamics

magnetic field

magnetic field measurements weighted by detected muon decays

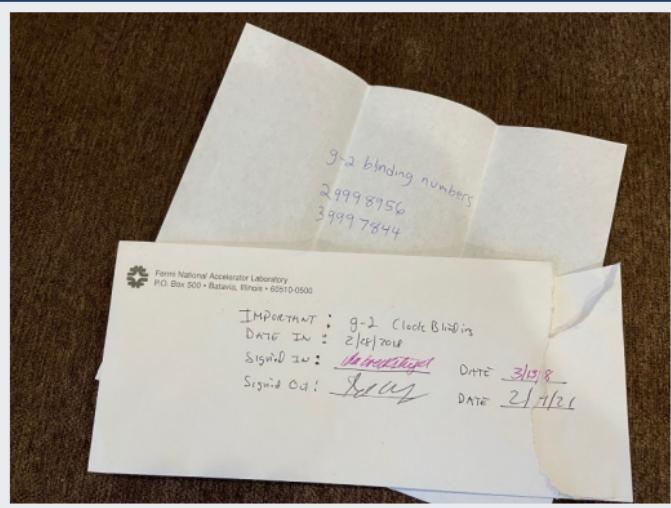

Blinding procedures (f_{clock})

- ▶ 40 MHz base nominal clock used for ω_a data acquisition modified with random ± 25 ppm offset
- ▶ secret offset conserved by two people outside the collaboration
- ▶ each Run is separately blinded
- ▶ second software blinding offset for each of the independent ω_a analysis groups (honor-code based)

blinding of 2018 Run

blinded clock for 2018

Reconstruction of positron energy deposits in calorimeters

readout

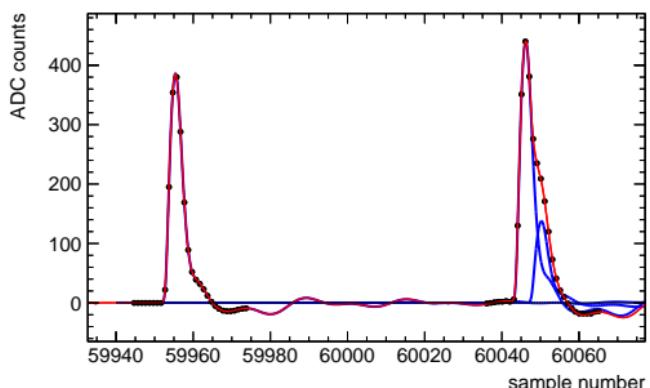

- ▶ record SiPM samples for all deposits > 50 MeV

fit using crystal pulses templates

- ▶ get template pulse for each crystal from data
- ▶ samples fit to one or more superposed templates

two reconstruction algorithms

- ▶ local: fit individual crystals
- ▶ global: global fit over multiple crystals

Early to late effects

- ▶ any unaccounted variation over time during the fill perturbs the ω_a fit result

ω_a fit bias from muon loss

- ▶ muon loss over time adds up to muon decay \Rightarrow fit model imperfect $\Rightarrow \omega_a$ fit bias

ω_a fit bias from phase variation due to muon loss

- ▶ muon sample polarization depends on momentum due to muon production chain
- ▶ muon polarization at injection is fit by fixed phase parameter φ , but actually $\varphi = \varphi(p)$
- ▶ muon loss depends on momentum, shifting the sample average over time $p = p(t)$
- ▶ \Rightarrow effective phase changes with time, $\varphi = \varphi(p(t))$ and at first order $\frac{d\varphi}{dt} = \frac{d\varphi}{dp} \frac{dp}{dt} \simeq \varphi'$
- ▶ \Rightarrow bias on ω_a : $\cos(\omega_a t + \varphi) \simeq \cos(\omega_a t + \varphi_0 + \varphi' t) = \cos[(\omega_a + \varphi')t + \varphi_0]$

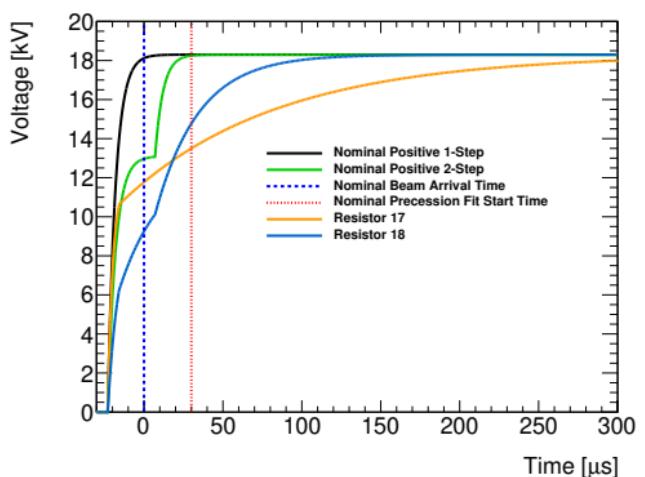

other accounted early to late effects

- ▶ calorimeter gain, pileup, beam average position and spread, ...
- ▶ some effects modeled in ω_a fit, other effects included as corrections

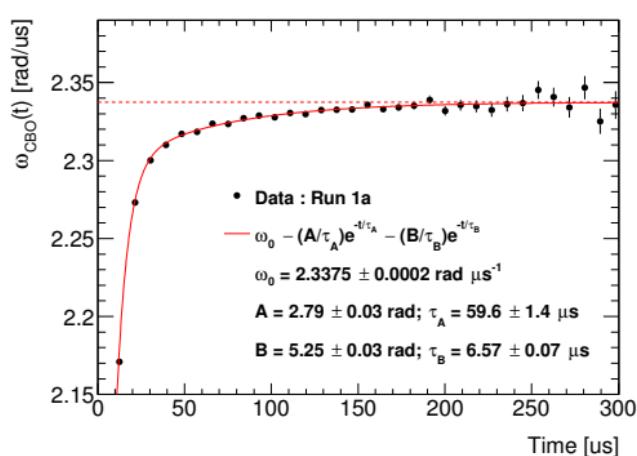

Run 1 difficulties

- ▶ two damaged resistors in one quadrupole increased high voltage switch-on time
⇒ quadrupole high voltage, hence beam position and spread, varied during the fill
- ▶ early-to-late variation of effective muon sample polarization phase
- ▶ varying CBO parameters had to be included in the fit model
- ▶ worse focusing of beam position and spread increased E-field and pitch corrections

quadrupole HV nominal vs. measured

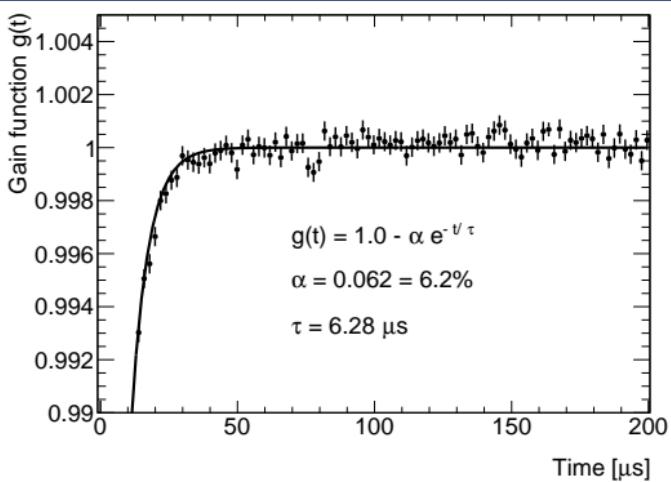

variation of CBO frequency

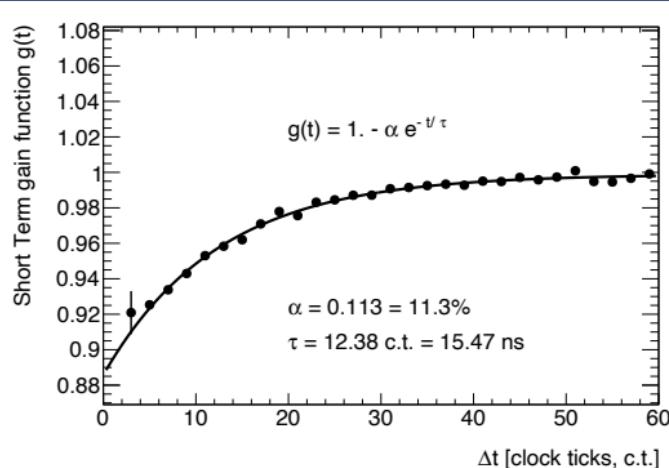

Calorimeter gain variation, corrected in reconstruction

- ▶ SiPM gain is reduced by occurrence of preceding hits
- ▶ gain monitored by reading back reference laser light pulses injected in PbF_2 crystals
- ▶ positron energy measurement from SiPM readout corrected for average measured gain loss

μs time scale SiPM power supply recovery time

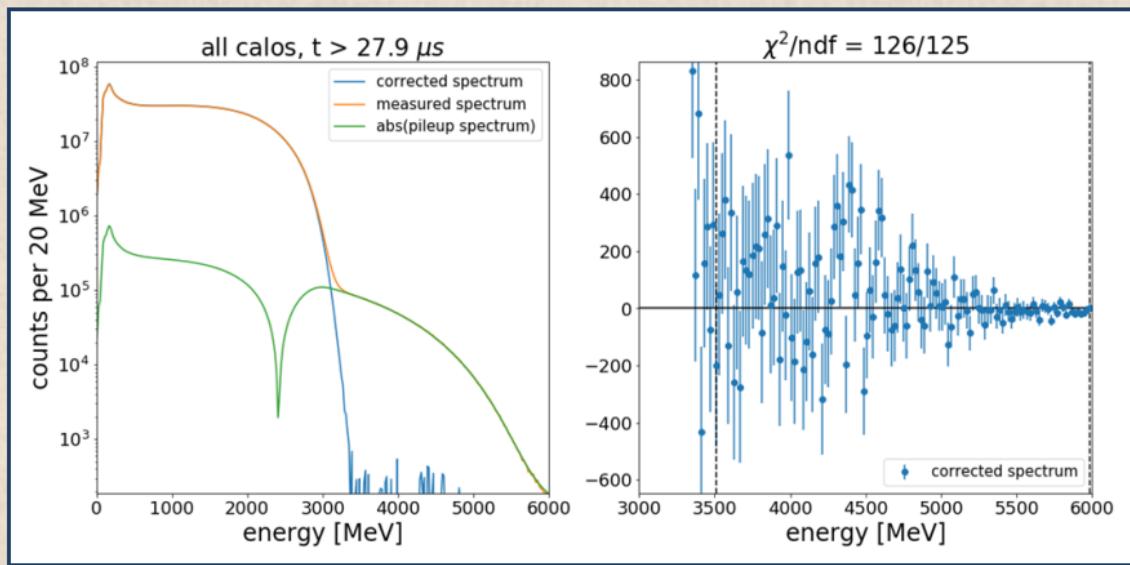

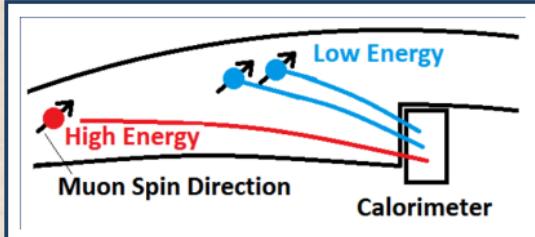

ns time scale SiPM pixel recovery time

Pileup statistically subtracted before fitting

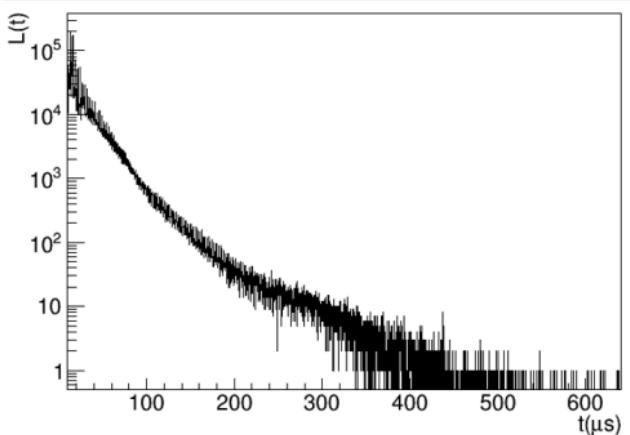

- ▶ three different methods have been used by 6 analysis groups

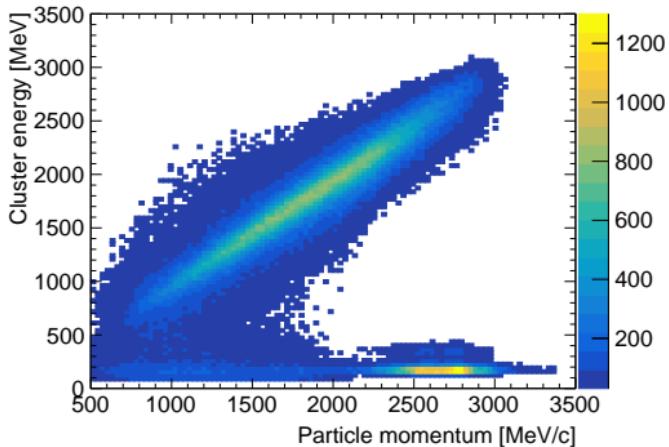

Lost muons modeled in fit function

- ▶ some muons hit collimators and are lost
- ▶ muon loss rate during a fill measured with 3-4-5 coincidences of m.i.p. on calorimeters
- ▶ overall normalization of muon loss included as fit parameter

muon loss vs. time

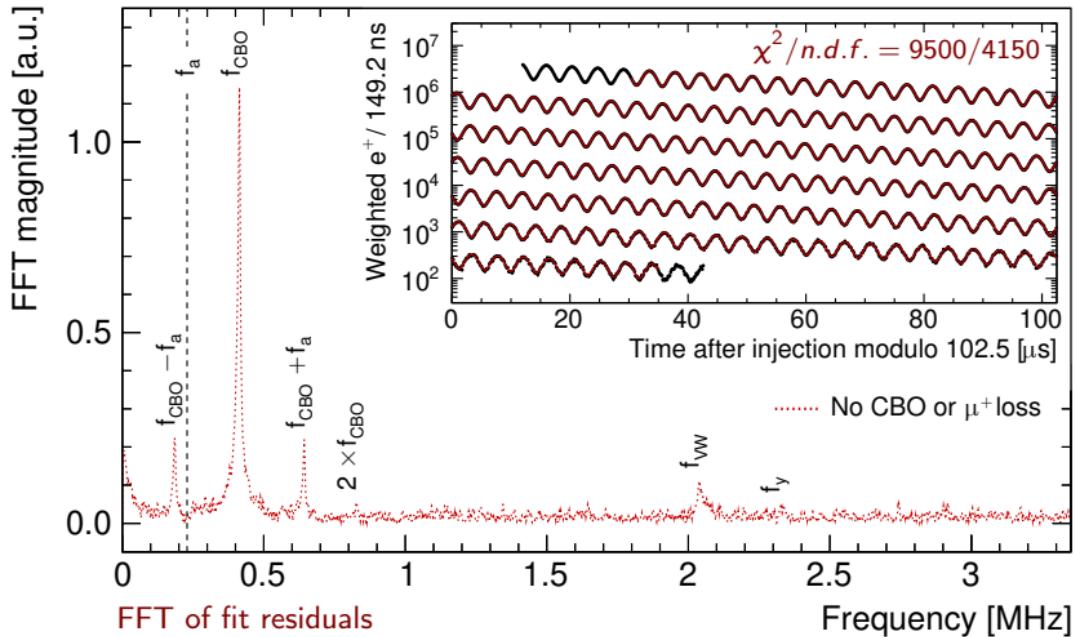

energy in calorimeter vs. momentum in tracker

Muon precession, 5 parameters fit

5-parameters fit to number of positron decays with $E > \sim 1.7$ GeV, binned over time, from 30 to 650 μ s

$$N(t) = N_0 e^{-t/\tau} [1 + A \cos(\omega_a t + \varphi)]$$

Muon precession, 22-parameters ω_a fit

- ▶ include beam dynamics oscillations of beam position and spread
- ▶ include effect of muon loss on collimators
- ▶ include effects of damaged quadrupole resistors

$$N_0 e^{-\frac{t}{\gamma\tau}} (1 + A \cdot A_{BO}(t) \cos(\omega_a t + \varphi + \varphi_{BO}(t))) \cdot N_{CBO}(t) \cdot N_{VW}(t) \cdot N_y(t) \cdot N_{2CBO}(t) \cdot \Lambda(t)$$

$$A_{BO}(t) = 1 + A_A \cos(\omega_{CBO}(t) \cdot t + \varphi_A) e^{-\frac{t}{\tau_{CBO}}}$$

$$\varphi_{BO}(t) = A_\varphi \cos(\omega_{CBO}(t) \cdot t + \varphi_\varphi) e^{-\frac{t}{\tau_{CBO}}}$$

$$N_{CBO}(t) = 1 + A_{CBO} \cos(\omega_{CBO}(t) \cdot t + \varphi_{CBO}) e^{-\frac{t}{\tau_{CBO}}}$$

$$N_{2CBO}(t) = 1 + A_{2CBO} \cos(2\omega_{CBO}(t) \cdot t + \varphi_{2CBO}) e^{-\frac{t}{2\tau_{CBO}}}$$

$$N_{VW}(t) = 1 + A_{VW} \cos(\omega_{VW}(t) \cdot t + \varphi_{VW}) e^{-\frac{t}{\tau_{VW}}}$$

$$N_y(t) = 1 + A_y \cos(\omega_y(t) \cdot t + \varphi_y) e^{-\frac{t}{\tau_y}}$$

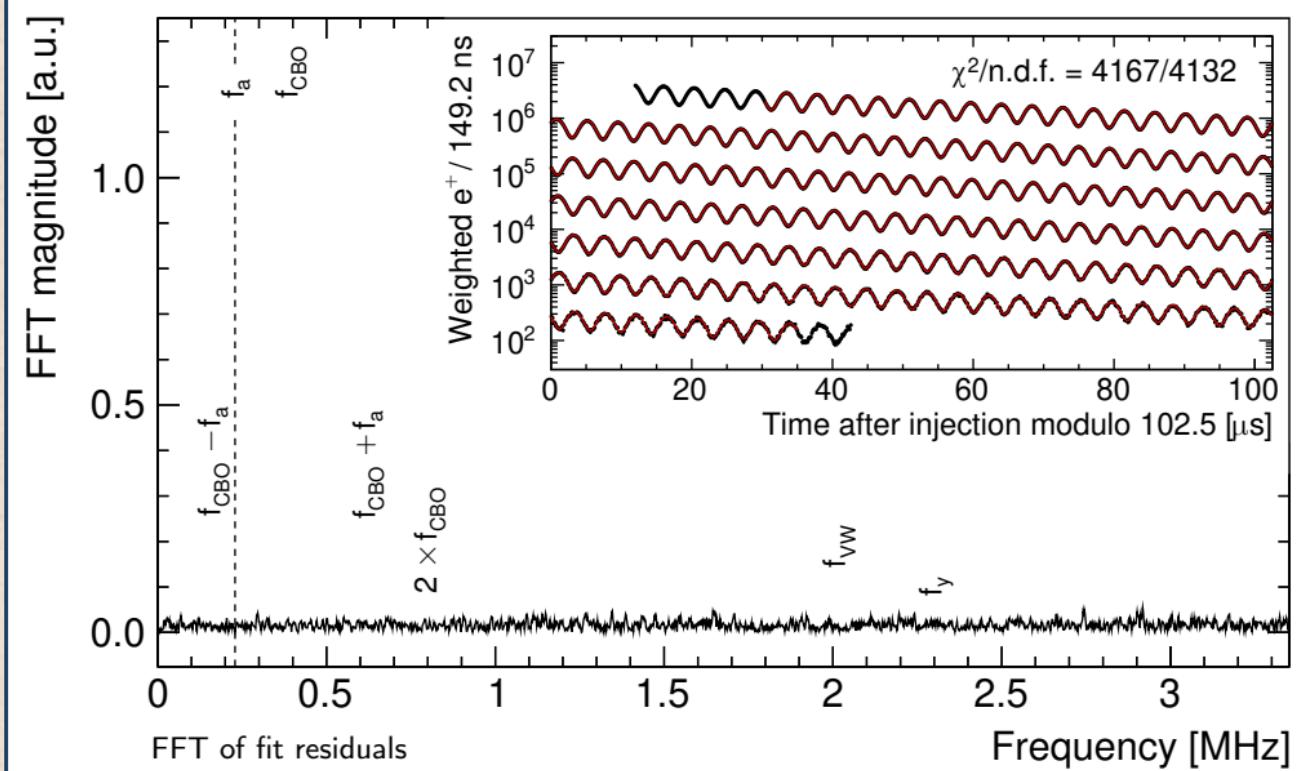

$$\Lambda(t) = 1 - k_{LM} \int_{t_0}^t L(t') e^{t'/\tau} dt'$$

$$\omega_{CBO}(t) = \omega_0^{CBO} + \frac{A}{t} e^{-\frac{t}{\tau_A}} + \frac{B}{t} e^{-\frac{t}{\tau_B}}$$

$$\omega_y(t) = F \omega_{CBO}(t) \sqrt{2\omega_c/F \omega_{CBO}(t) - 1}$$

$$\omega_{VW}(t) = \omega_c - 2\omega_y(t)$$

22 parameters ω_a fit has $\chi^2 / \text{n.d.o.f.}$ consistent with 1

6 analysis groups, 4 analysis methods, 11 ω_a fits

4 analysis methods

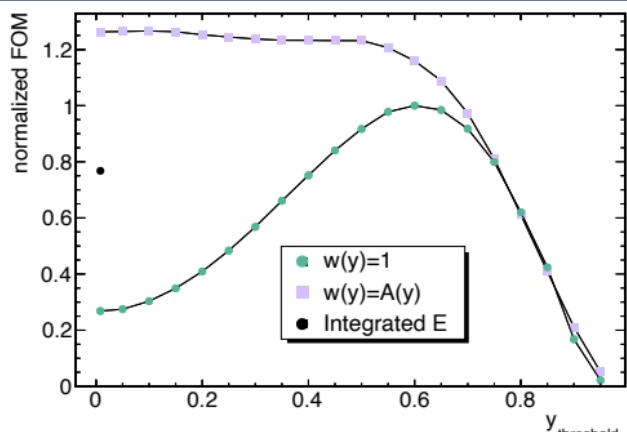

- ▶ T (threshold): $\sum N(E_{e^+})$ $E_{e^+} > 1.7 \text{ GeV}$
- ▶ R (ratio): (see below) $E_{e^+} > 1.7 \text{ GeV}$
- ▶ A (asymmetry): $\sum A \cdot N(E_{e^+})$ $E_{e^+} > 1.0 \text{ GeV}$
- ▶ Q (charge): \sum energy deposits no threshold

ratio method

- ▶ randomly split time-binned positron decays in 4 sets
- ▶ displace time of two sets by $\pm T_a/2$
- ▶ ratio of 2 linear combinations can be fitted with just $A \cos(\omega_a t + \varphi)$ (instead of 5-par. fit)

- ▶ two reconstruction algorithms
- ▶ three pileup correction algorithms

FOM vs. E/E_{\max} threshold for T/R, A, Q

 - ▶ Run number
 - ▶ time of day
 - ▶ positron energy bin
 - ▶ position within calorimeter
 - ▶ ...

Average of 11 ~critically correlated measurements with imprecise correlation

11 measurements
with different analyses
on same data sample

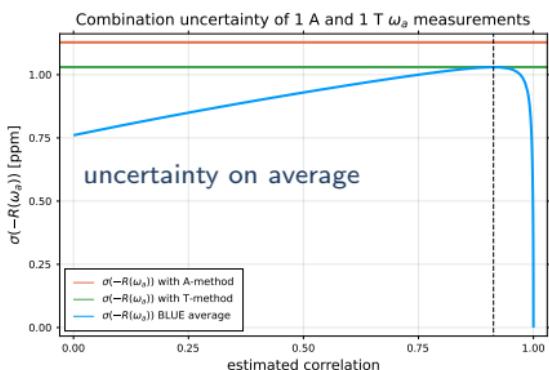

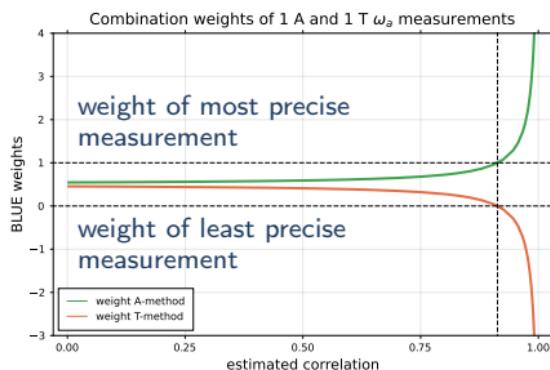

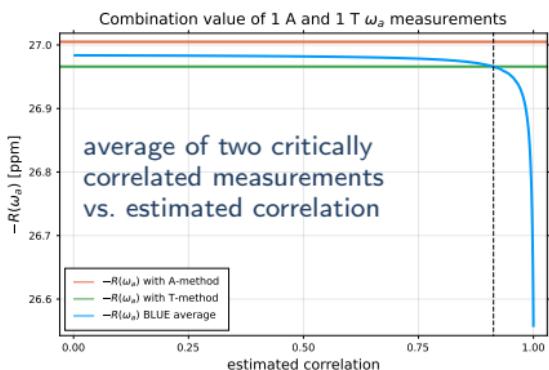

statistical correlation
estimated with toy MC

systematics correlation
conservatively 100%

uncertainty on average reduced
as if there were 45% more data

Critical correlation: $C_{ij}^{\text{crit}} = \rho^{\text{crit}} = \min(\sigma_i, \sigma_j) / \max(\sigma_i, \sigma_j)$ ($i \neq j$)

Least χ average of 2 meas. around ρ ρ^{crit}

- unstable vs. value of estimated ρ
- Glen Cowan, Stat. Data Analysis, sec. 7.6.1
- Valassi & Chierici 2014, EPJC 74 (2014) 2017
- but no literature really appropriate for our case

ω_a^m staged A-method average for measurements on same dataset

- ▶ A-method statistically optimal for ideal measurement with only Poisson uncertainties
- ▶ in Run 1 we are close to these conditions because Poisson statistical uncertainties dominate
- ▶ in this approximation, the optimal combination corresponds to just average the A-method measurements
- ▶ ⇒ combine just the 4 A-method measurements with equal weights, for each dataset
 - ▶ but, taking into account that there is some decorrelation due to using two reconstructions
⇒ average first A-measurements using the same reconstruction, then average across reconstructions

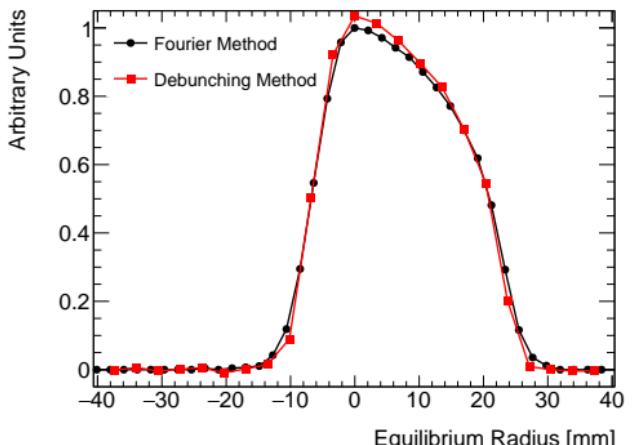

ω_a^m uncertainties

	[ppb]
total uncertainty	437
statistical	434
systematics	56
- Time randomization	9
- Gain	8
- Pileup	35

- Early to late effect	17

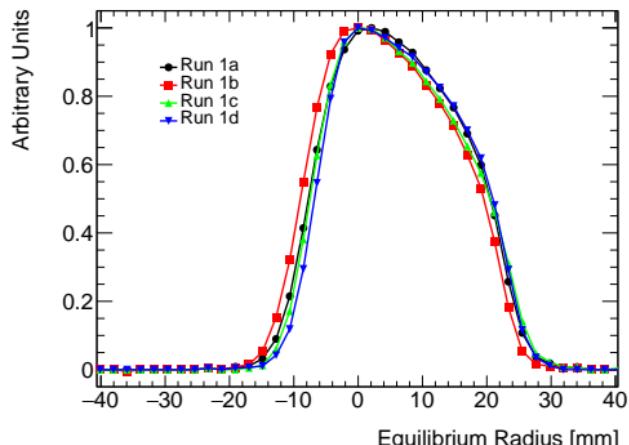

Electric field correction $C_e = +489 \pm 53$ ppb

- ▶ compute momentum distribution from electrons detected at early times after injection
 - ▶ using cosine Fourier transform of rate vs. time
 - ▶ measuring change of shape of rectangular bunches (debunching)
- ▶ compute radial muon distribution from momentum distribution
- ▶ compute electric field contribution to ω_a due to quadrupoles electric field
- ▶ Run 1 kicker strength was insufficient \Rightarrow extra radial displacement and C_e

cosine Fourier vs. debunching method

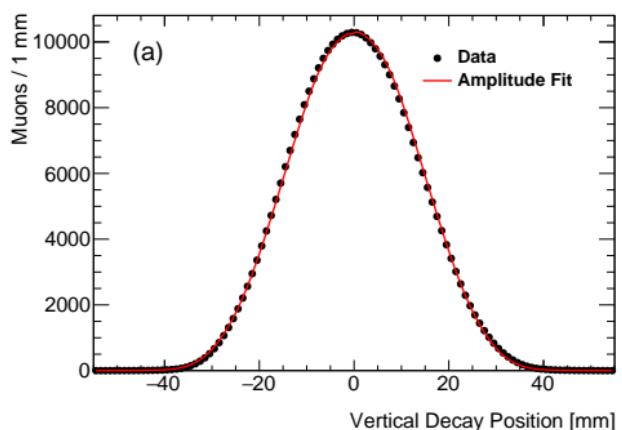

radial distributions in the four datasets

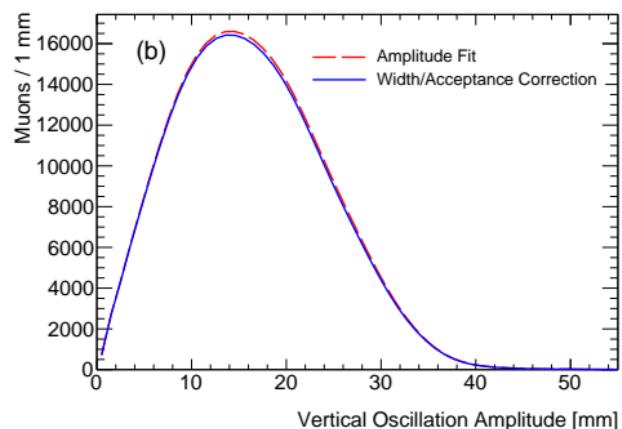

Pitch correction $C_p = +180 \pm 13$ ppb

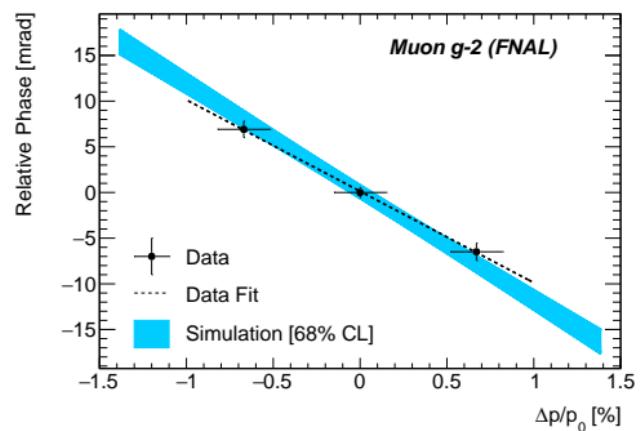

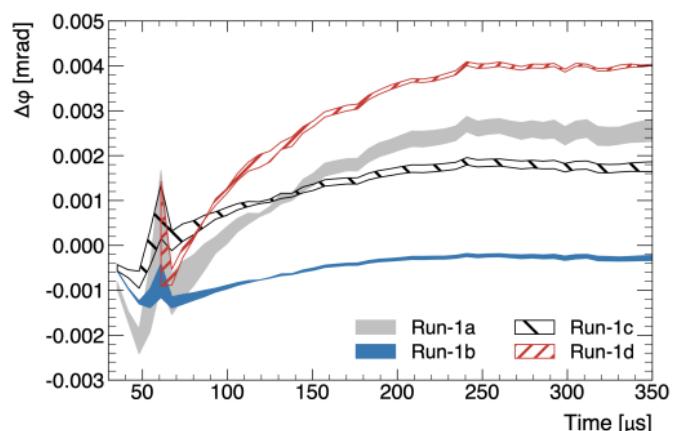

- ▶ reconstruct muon vertical position from decay electrons measured on trackers
- ▶ compute corresponding pitch correction to ω_a

vertical decay vertices distribution

vertical oscillation amplitude distribution

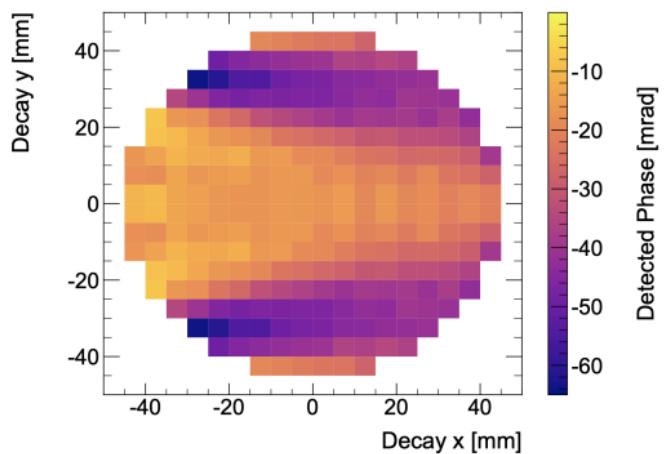

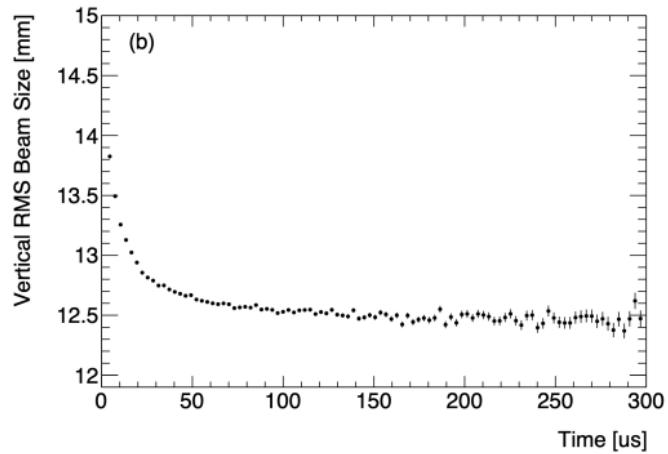

Lost muons phase-variation effect correction $C_{\text{ml}} = -11 \pm 5 \text{ ppb}$ φ / p measured on dedicated runsestimated φt due to muon loss

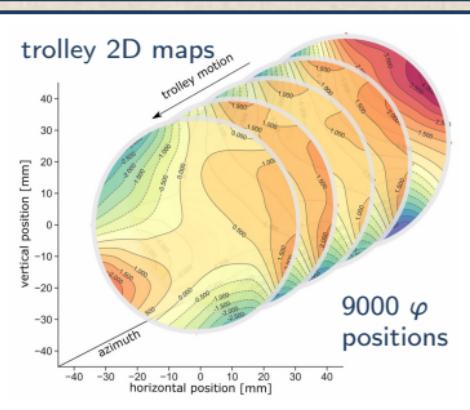

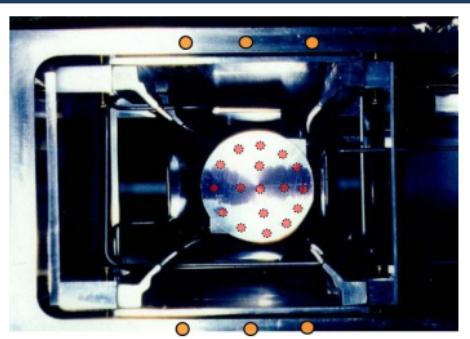

Phase-Acceptance correction $C_{pa} = -158 \pm 75$ ppb

- ▶ effective phase variation due to variation of beam horizontal and vertical position and spread
- ▶ example: $\Delta\omega_a = \frac{d\varphi}{dt} = \frac{d\varphi}{dY_{RMS}} \cdot \frac{dY_{RMS}}{dt}$
- ▶ obtained with simulation
- ▶ measured with trackers and extrapolated to whole ring with beam dynamics simulations

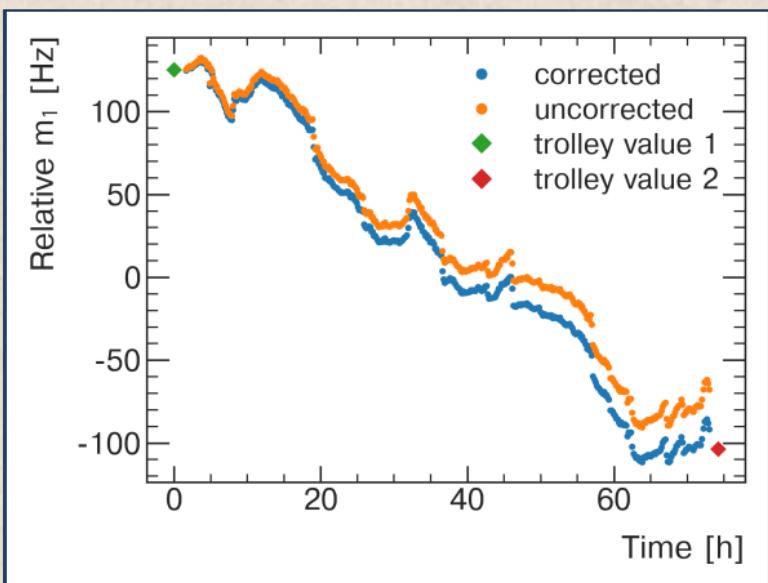

phase as a function of muon position

variation of Y_{RMS} 

Measuring the magnetic field with fixed and trolley probes

- ▶ 378 fixed probes measure continuously the magnetic field
 - ▶ 17-probes trolley run along muons path every ~ 3 days
 - ▶ fixed probes measurements corrected using trolley measurements

Measuring the magnetic field: calibration of probes

calibration

- ▶ each trolley probe calibrated with **absolute cylindrical probe** placed in the same position inside the storage ring
- ▶ absolute cylindrical probe calibrated to reference **absolute spherical probe** in MRI magnet at Argonne National Laboratory
- ▶ absolute spherical probe consistent with novel absolute ${}^3\text{He}$ probe
- ▶ 17 probes calibration uncertainty 20 – 48 ppb

reference temperature

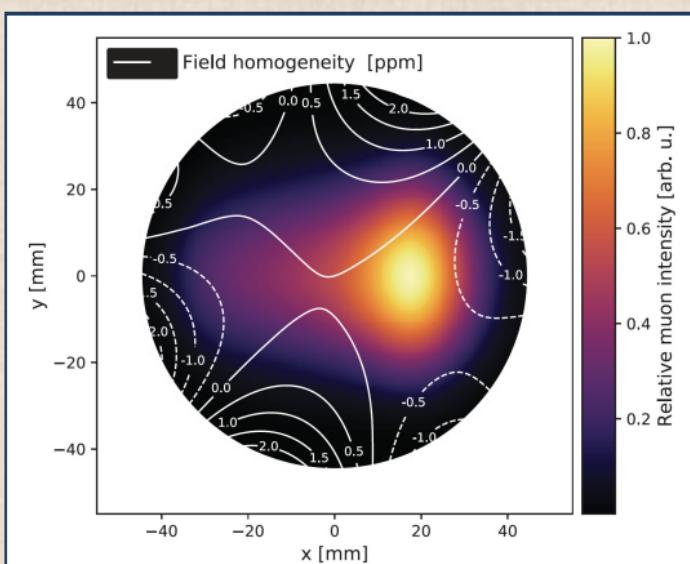

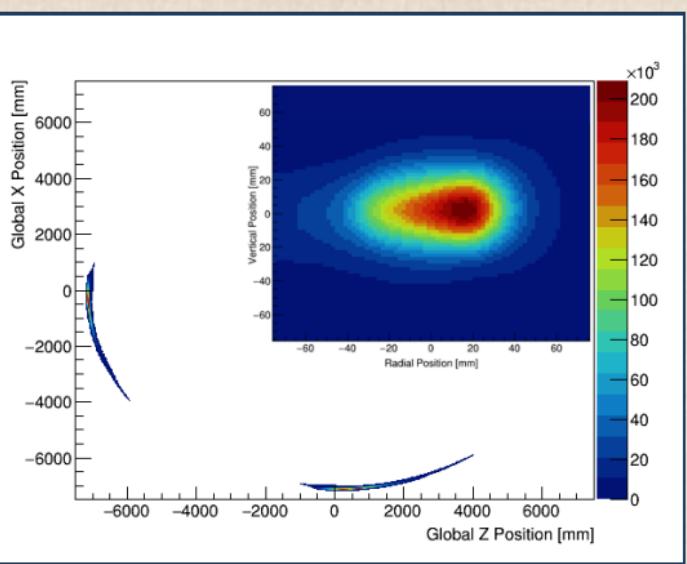

- ▶ magnetic field measurements corrected to be expressed as $\omega'_p(T)$, precession frequency of shielded proton spin in spherical water sample at reference temperature of 34.7 °C

absolute spherical probe

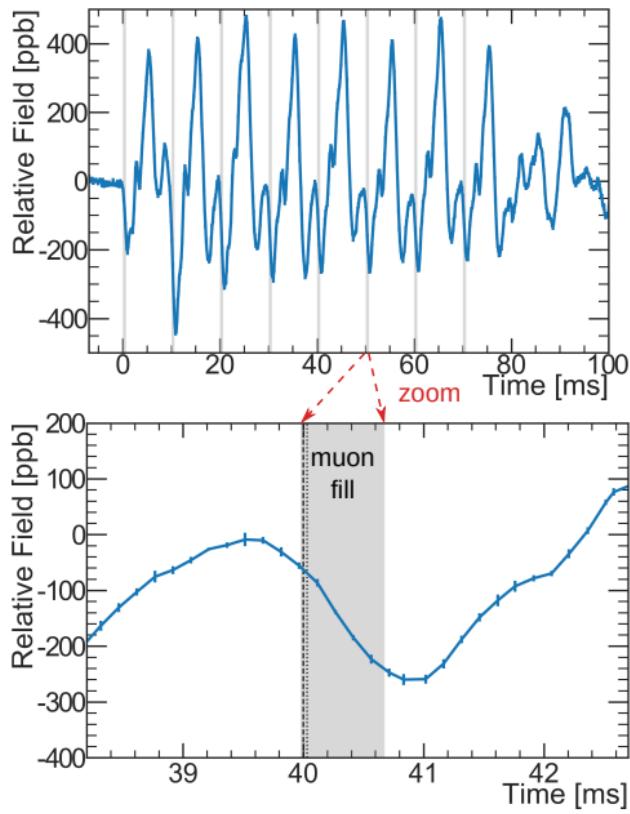

Compute the magnetic field experienced by the muons to 56 ppb

- tracker reconstructs muons decay vertices in parts of storage region
- beam dynamics simulation used to extrapolate to whole storage region
- magnetic field map averaged over muon distribution
- two independent groups did the measurement, one additional group the calibration

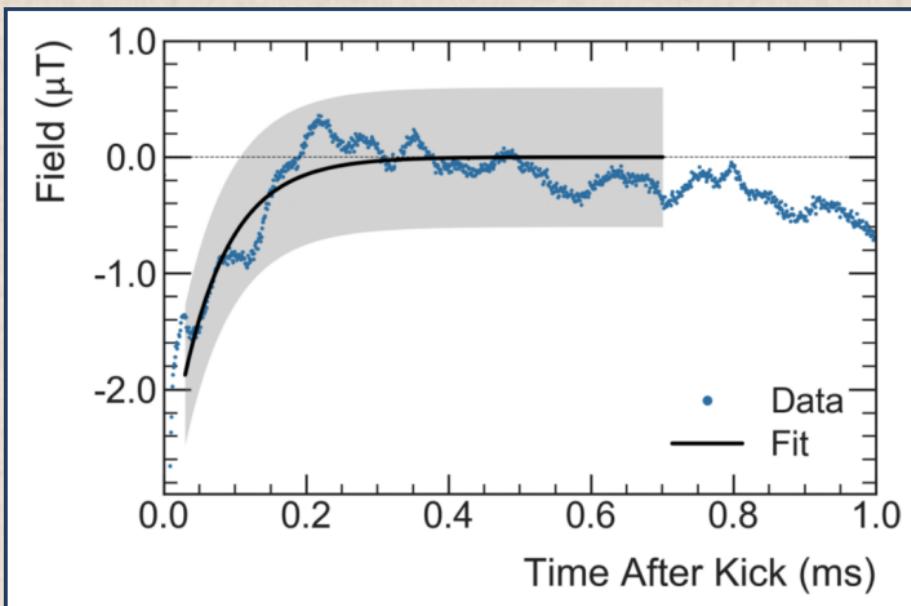

Quadrupoles transient field correction $B_q - 17 \pm 92$ ppb

- quadrupoles are pulsed
(to prevent static charge accumulation)
- plates vibration perturbs magnetic field
- special NMR probes measure the transient field perturbation in muon region
- large uncertainty because mapping incomplete
will improve in Run 2+

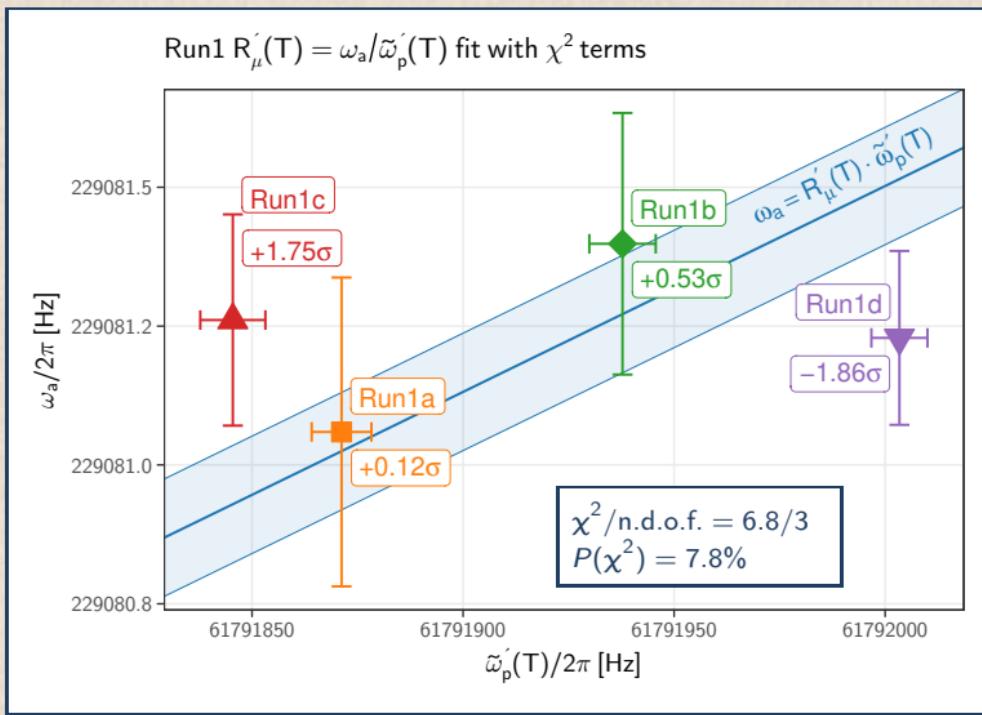

Kicker transient field correction $B_k = -27 \pm 37$ ppb

- ▶ kicker pulsed before start of fit window
- ▶ induced eddy currents perturb magnetic field inside fit window
- ▶ magnetic field perturbation measured with a Faraday effect magnetometer

All corrections and uncertainties estimated before unblinding

	Correction	Uncertainty	Design goal
ω_a^m (statistical)	–	434	100
ω_a (systematic)	–	56	
base clock	–	2	
C_e	489	53	
C_p	180	13	
C_{ml}	-11	5	
C_{pa}	-158	75	
ω_a beam dynamics corrections ($C_e + C_p + C_{ml} + C_{pa}$)	499	93	
ω_a total systematic	499	109	70
$\omega'_p(T)(x, y, \varphi)$	–	54	
$M(x, y, \varphi)$	–	17	
$\langle \omega'_p(T)(x, y, \varphi) \times M(x, y, \varphi) \rangle$	–	56	
B_q	-17	92	
B_k	-27	37	
$\tilde{\omega}'_p(T)$ transient fields corrections ($B_q + B_k$)	-44	99	
$\tilde{\omega}'_p(T)$ total	44	114	70
$\omega_a/\tilde{\omega}'_p(T)$ total systematic	544	157	100
external measurements	–	25	
total [correction is for $\omega_a/\tilde{\omega}'_p(T)$]	544	462	140

$\omega_a, \tilde{\omega}_p'^T$ for the four Run 1 datasets

- reported χ^2 terms are larger than one can guess on the plot because uncertainties are partly correlated

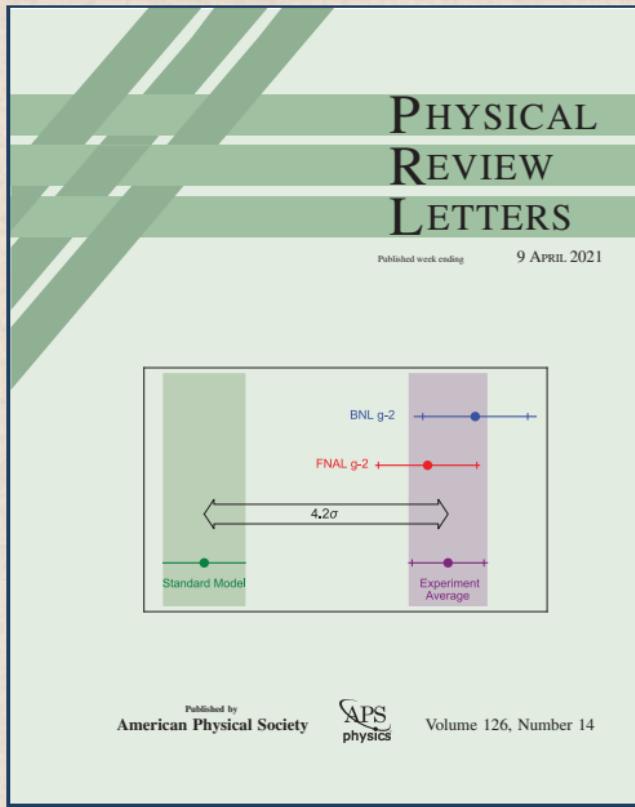

We decided to unblind in a remote meeting of the whole collaboration

First FNAL Muon $g-2$ result

- ▶ a_μ (BNL) recomputed from R_μ (BNL) like a_μ (FNAL)
- ▶ included correlation due to external measurements, assumed no other correlation between BNL and FNAL

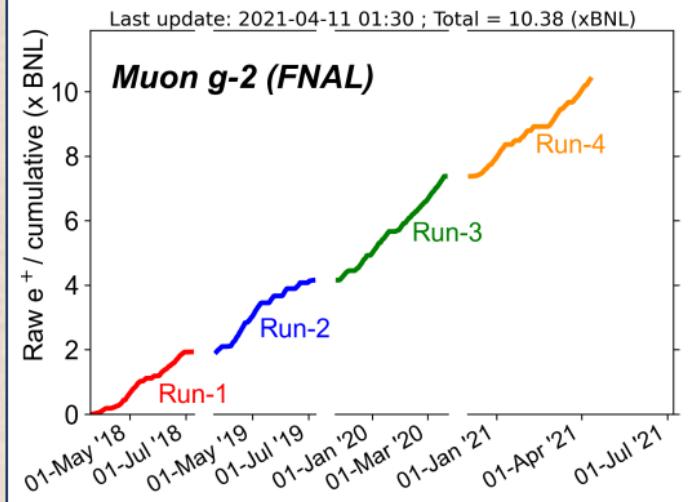

Three papers published on April 7, 2021, a fourth one accepted

- ▶ Measurement of the Positive Muon Anomalous Magnetic Moment to 0.46 ppm
[doi:10.1103/PhysRevLett.126.141801](https://doi.org/10.1103/PhysRevLett.126.141801)
- ▶ Measurement of the anomalous precession frequency of the muon in the Fermilab Muon $g-2$ Experiment
[doi:10.1103/PhysRevD.103.072002](https://doi.org/10.1103/PhysRevD.103.072002)
- ▶ Magnetic Field Measurement and Analysis for the Muon $g-2$ Experiment at Fermilab
[doi:10.1103/PhysRevA.103.042208](https://doi.org/10.1103/PhysRevA.103.042208)
- ▶ Beam dynamics corrections to the Run-1 measurement of the muon anomalous magnetic moment at Fermilab
[arXiv:2104.03240 \[physics.acc-ph\]](https://arxiv.org/abs/2104.03240)

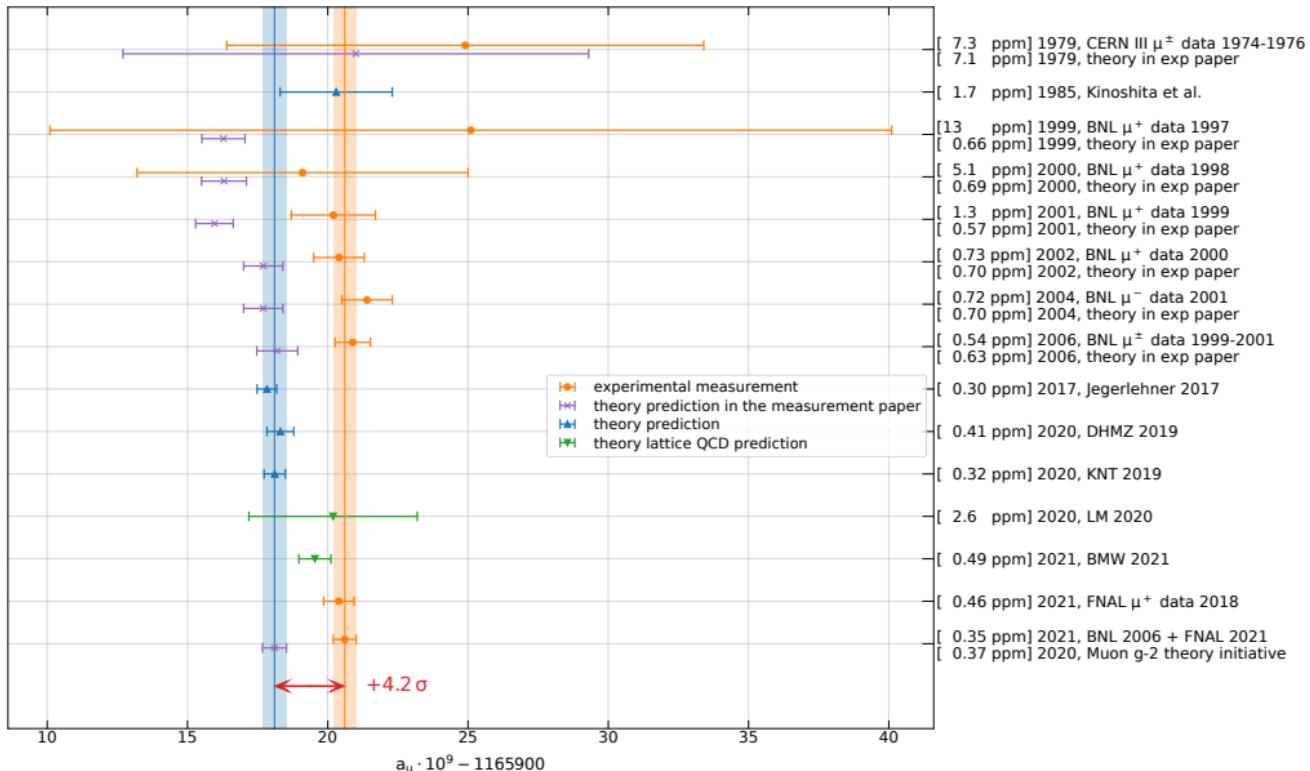

Outlook

- ▶ Run 1 is 6% of our design goal sample
- ▶ measurement using Run 2+3 data in \sim 1 year
- ▶ improvements ongoing also on theory side

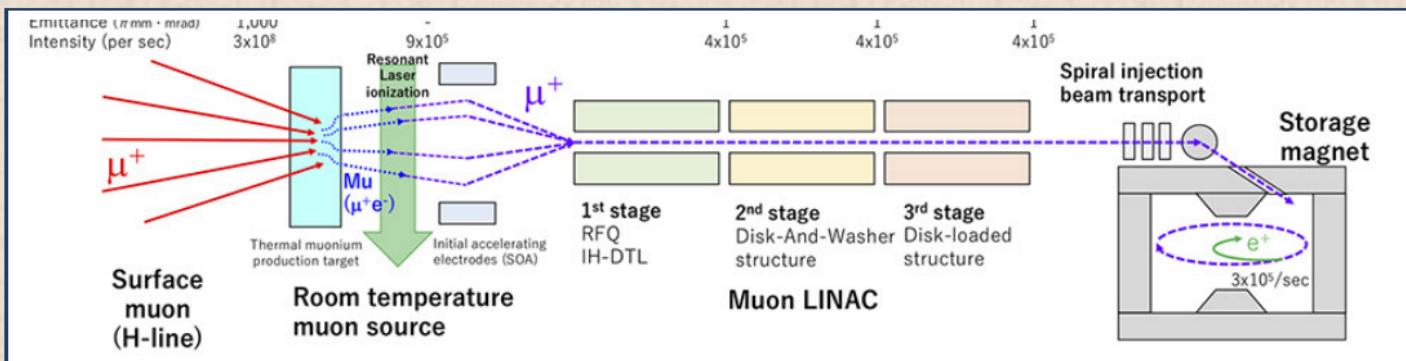

Backup Slides

a_μ measurements and predictions 1979 – April 2021 (incomplete collection)

Muon g-2/EDM experiment at J-PARC

- ▶ 50% polarized 300 MeV muons
- ▶ small 3.0 T magnet
- ▶ no electric field, low focusing magnetic field
- ▶ silicon tracker instead of calorimetry
- ▶ $5.7 \cdot 10^{11}$ reconstructed electrons
- ▶ 0.45 ppm statistical uncertainty goal

Main ω_a measurement systematics mentioned in E989 TDR

	E821 [ppb]	E989 improvement plans	goal [ppb]	Run 1 [ppb]
gain changes	120	better laser calibration low-energy threshold	20	20
pileup	80	low-energy samples recorded calorimeter segmentation	40	35
lost muons	90	better collimation in ring	20	5
CBO	70	higher n value (frequency) better match of beamline to ring	<30	38
E and pitch	50	improved tracker precise storage ring simulation	30	55
total	180		70	109

Investigations on T-A bias extended to Run 2
